Introduction

From April 2022 through March 2023 the Yellow Perch Task Group (YPTG) addressed the following charges:

- 1. Maintain and update the centralized time series of datasets required for population models and assessment including:
 - a. Fishery harvest, effort, age composition, biological and stock parameters.
 - b. Survey indices of young-of-year, juvenile and adult abundance, size-at-age and biological parameters.
 - c. Fishing harvest and effort by grid.
- 2. Report Recommended Allowable Harvest (RAH) levels for LEC TAC decisions.
- 3. Ensure population models are current and produce the most scientifically defensible and reliable method for estimating and forecasting abundance, recruitment, and mortality.
 - a. Evaluate the impact of recruitment indices on ADMB model results.
 - b. Evaluate ADMB model parameter sensitivity.
- 4. Supply needed technical support throughout the upcoming YPMP review process.

Charge 1: 2022 Fisheries Review and Population Dynamics

The lakewide total allowable catch (TAC) of Yellow Perch in 2022 was 7.185 million pounds. This allocation represented a 15% increase from a TAC of 6.238 million pounds in 2021. For Yellow Perch assessment and allocation, Lake Erie is partitioned into four management units (MUs; Figure 1.1). The 2022 TAC allocation was 3.038, 0.537, 3.082, and 0.528 million pounds for MUs 1 through 4, respectively. In March 2022 the Lake Erie Committee (LEC) applied the harvest policy within the Yellow Perch Management Plan to set the TAC. For MU1, the LEC set the TAC equal to 3.038 million pounds, which was a 20% increase from 2021. In MU2, the target fishing mortality rate was reduced to F=0.120, lowering the mean RAH and range. The target fishing mortality rate was reduced to ensure the spawning stock biomass in 2023 would not fall below the limit reference point, B_{msy}, with a probabilistic risk tolerance of 0.20 (i.e., P*). For MU2, the LEC set the TAC at 0.537 million pounds, which was equal to the mean RAH, representing a 13% decrease from 2021. For MU3, the LEC set the TAC at 3.082 million pounds, which was slightly lower than the mean RAH and a 20% increase from 2021. In MU4, the LEC set the TAC at 0.528 million pounds, which was the mean RAH and virtually unchanged from the 2021 TAC.

The lakewide harvest of Yellow Perch in 2022 was 3.400 million pounds, or 47% of the total 2022 TAC. This was a 3% increase from the 2021 harvest of 3.296 million pounds. Harvest from MUs 1 through 4 was 1.497, 0.296, 1.208, and 0.399 million pounds, respectively (Table 1.1). The portion of TAC harvested was 49%, 55%, 39%, and 76%, in MUs 1 through 4, respectively. In 2022, Ontario harvested 2.195 million pounds, followed by Ohio (0.988 million lbs.), New York (0.084 million lbs.), Michigan (0.068 million lbs.), and Pennsylvania (0.064 million lbs.).

Ontario's fraction of allocation harvested was 62% in MU1, 73% in MU2, 58% in MU3, and 103% in MU4 (see paragraph below regarding Ontario's harvest reporting and commercial ice allowance policy). Ohio fishers attained 43% of their TAC in the western basin (MU1), 40% in the west central basin (MU2), and 21% in the east central basin (MU3). Michigan anglers in MU1 attained 25% of their TAC. Pennsylvania fisheries harvested 14% of their TAC in MU3 and 1% of their TAC in MU4. New York fisheries attained 51% of their TAC in MU4. Ontario's portion of the lakewide Yellow Perch harvest in 2022 (65%) was similar to 2021 (65%; Table 1.1). Ohio's proportion of lakewide harvest was 29% in both 2021 and 2022, and harvest in Michigan, Pennsylvania, and New York waters combined represented around 6% of the lakewide harvest in 2022.

Ontario continued to employ a commercial ice allowance policy implemented in 2002, by which 3.3% is subtracted from commercial landed weight. This step was taken so that ice was not debited towards fishers' quotas. Ontario's landed weights in the YPTG report have not been adjusted to account for ice content. Ontario's reported Yellow Perch harvest in tables and figures is represented exclusively by the commercial gill net fishery. Yellow Perch sport harvest from Ontario waters is assessed periodically, which last occurred in 2014, but is not reported here. Reported sport harvests for Michigan, Ohio, Pennsylvania, and New York are based on creel survey estimates. Ohio, Pennsylvania, and New York trap net harvest and effort are based on commercial catch reports of landed fish. Additional fishery documentation is available in annual agency reports.

Harvest, fishing effort, and fishery harvest rates are summarized from 2013 to 2022 by management unit, year, agency, and gear type in Tables 1.2 to 1.5. Trends across a longer time series (1975 to 2022) are depicted graphically for harvest (Figure 1.2), fishing effort (Figure 1.3), and harvest rates (Figure 1.4) by management unit and gear type. The spatial distributions of harvest (all gears) and effort by gear type for 2022 in ten-minute interagency grids are presented in Figures 1.5 through 1.8.

Ontario's Yellow Perch harvest from large mesh (3 inches or greater stretched mesh) gill nets in 2022 was 2%, 14%, 3%, and <1% of the gill net harvest in management units 1 - 4, respectively. Harvest, effort, and catch per unit effort from (1) small mesh Yellow Perch effort (2.25"=<stretched mesh<3") and (2) larger mesh sizes, are distinguished in Tables 1.2 to 1.5. Harvest from targeted small mesh gill nets in 2022 decreased by 19% in MU1, increased 45% in MU3 and 2% in MU4, and changed less than 1% in MU2 in relative to 2021. Ontario trap nets, which primarily target white bass, harvested zero yellow perch in 2022. Ontario commercial Rainbow Smelt trawlers incidentally caught Yellow Perch in management units 3 and 4, and this harvest is included in Tables 1.4 to 1.5. In 2022, 21 pounds of Yellow Perch were harvested in trawl nets in MU3 and 782 pounds were harvested in MU4.

Targeted (i.e., small mesh) gill net effort in 2022 decreased from 2021 effort in all units (MU1 – MU4) by 18%, 24%, 5%, and 37% respectively. Targeted gill net harvest rates in 2022 decreased less than 2% relative to 2021 rates in MU1, while increasing in MU2 by 33%, MU3 by 53%, and MU4 by 62% (Figure 1.4).

Compared to 2021, sport harvest in 2022 in U.S. waters increased in MU1 (537,863 lbs.), MU2 (20,201 lbs.), and MU4 (70,019 lbs.) by 5%, 297%, and 46%, respectively, while decreasing 56% to less than 6,761 pounds in MU3 (Figure 1.2). Angling effort in U.S. waters during 2022 was highest in MU1 and lowest in MU3. Angler effort in 2022 increased 1303% from record low angling effort during 2021 in MU2 and by 64% in MU4, decreased 53% in MU3, and remained relatively unchanged from 2021 in MU1 (Figure 1.3). In 2022, angling effort in U.S. waters of MU3 at 6,120 hours was at its lowest in the time series, while effort of 26,634 hours in MU2 was the third lowest in time series (Figure 1.3).

Sport fishing harvest rates are commonly expressed as fish harvested per angler hour for those seeking Yellow Perch. These harvest rates are presented in Tables 1.2 to 1.5. Compared to 2021 rates, harvest per angler hour decreased in Michigan (-11%) and increased in Ohio waters of MU1 (+5%). In the central basin, sport angler harvest rate increased in the Ohio waters of MU2 (+513%) although the rate of 0.5 fish/hour is still one of the lowest in the time series, and decreased in the Ohio (-63%) waters of MU3 while increasing in Pennsylvania (+30%) waters of MU3. In MU4, harvest rates declined in both New York waters (-7%) and Pennsylvania waters (-100%), however there was a large difference in these MU4 areas with a 1.9 fish/hour rate in New York and near zero fish/hour in Pennsylvania.

Trap net harvest increased by 3% in MU1, 20% in MU3, and 31% in MU4 while decreasing by 16% in MU2 compared to 2021 (Tables 1.2 to 1.5). Trap net effort (lifts) in 2022 increased in MU1, MU2, MU3, and MU4 by 32%, 87%, 18%, and 76% respectively, relative to

2021 trap net effort. Total trap net effort during 2022 was highest in MU1 at 4943 lifts. Trap net harvest rates increased slightly from 2021 rates in MU3 (+2%), but declined by 22%, 55%, 25% in MU1, MU2, and MU4, respectively.

Age Composition and Growth

Lakewide, age-3 fish (2019 YC) contributed the most to the Yellow Perch harvest (47%), followed by age-2 fish (2020 YC; 26%), with age-4, age-5, and age-6-and-older fish contributing 18%, 4%, and 3%, respectively; Table 1.6). In MU1, age-2 fish (2020 year class, 41%) contributed most to the fishery, followed by age-3 (2019 year class, 27%) and age-4 fish (2018 year class, 24%). In MU2, age-3 fish (2019 year class, 53%), age-4 fish (2018 year class, 20%) and age-2 fish (2020 year class 17%) contributed most to the fishery. In MU3, age-3 fish (2019 year class, 70%) contributed most to the fishery, with all other age-classes individually accounting for less than 13% of harvest. In MU4, age-3 (2019 year class, 51%) and age-2 (2020 year class, 30%) fish contributed most to the harvest.

The task group continues to update Yellow Perch growth data in: (1) weight-at-age values recorded annually in the harvest and (2) length- and weight-at-age values taken from interagency trawl and gill net surveys. These values are applied in the calculation of population biomass and the forecasting of harvest in the approaching year. Therefore, changes in weight-at-age factor into the changes in overall population biomass projections and determination of recommended allowable harvest (RAH).

Statistical Catch-at-Age Analysis

Population size for each management unit was estimated by statistical catch-at-age analysis (SCAA) using the Auto Differentiation Model Builder (ADMB) computer program (Fournier et al. 2012). In 2022, the YPTG continued to use the ADMB model developed by the Quantitative Fisheries Center (QFC) at Michigan State University (referred to as the Peterson-Reilly or PR model) as part of the Lake Erie Percid Management Advisory Group (LEPMAG) review of Yellow Perch management on Lake Erie.

The PR model uses harvest and effort data from commercial gill net, commercial trap net, and recreational fisheries within each MU. Survey catch-at-age of age-2 and older fish from gill net and trawl surveys are also incorporated. In addition, age-0 and age-1 recruitment data are incorporated into the model as a recruitment index. The PR model estimates selectivity for all

ages in the fisheries and surveys. There is a commercial gill net selectivity block beginning in 1998. Catchabilities for all fisheries and surveys vary annually as a correlated random walk. The model is fit to total catch and proportions-at-age (multinomial age composition) as separate data sets.

Running the PR model is a three-step process. In the first step, an ADMB model without recruitment data is run iteratively until the maximum effective sample size for the multinomial age composition stabilizes (i.e., does not change by more than 1-2 units). Second, age-2 abundance estimates from the first model are combined with age-0 and age-1 recruitment data (from trawl and gill net assessment surveys) in a multi-model inference (MMI) R-based model to determine parameters for estimating recruitment. Recruitment data from the last nine years are removed from the model to minimize possible retrospective effects. Further, years with missing data in one or more data sets are removed from all data sets. Surveys missing data for the projection year (e.g., 2020 year class in the 2022 TAC year) are also removed from the analysis. A list of all possible non-redundant models is generated from the survey data and fit using the R-based glmulti package (Calcagno 2013). All models falling within 2 AIC units of the best model are used to generate the model-averaged coefficients. Surveys are not weighted equally in the final modelaveraged coefficients; each model may contain a different set of surveys and the models with lower AIC values are weighted more heavily and have greater influence on the recruitment predictions. Parameter estimates for the model-averaged coefficients for each MU are detailed in Appendix Table 2. A recruitment index is generated to estimate age-2 fish for each year class available in the recruitment data, using the age-0 and age-1 survey data. This process is repeated using just age-0 data, which is only used to estimate recruitment in two years' time. Data from trawl and gill net index recruitment series for the time period examined are presented in Appendix Table 3, and a key that summarizes abbreviations used for the trawl and gill net series is presented in Appendix Table 4.

In the third step, the recruitment index is added to the ADMB model, and this data set is used to inform age-2 abundance estimates within the objective function. This model is then run iteratively until the maximum effective sample size for the multinomial age composition stabilizes. Estimates of population size, from 2004 to 2022, and projections for 2023, are presented in Table 1.7. Abundance, biomass, survival, and exploitation rates are presented by management unit graphically for 1975 to 2022 in Figures 1.9 to 1.12. Mean weights-at-age from assessment surveys were applied to abundance estimates to generate population biomass estimates (Figure 1.10). Projections of abundance and biomass in 2023 are included in Figures 1.9 and 1.10.

Population abundance and biomass estimates are critical to monitoring the status of stocks and determining recommended allowable harvest.

Abundance estimates should be interpreted with several caveats. Inclusion of abundance estimates from 1975 to 2022 implies that the time series are continuous. Lack of data continuity for the entire time series weakens the validity of this assumption. Survey data from multiple agencies are represented only in the latter part of the time series (since the late 1980s); methods of fishery data collection have also varied. Some model parameters, such as natural mortality, are constrained to constants. This technique lessens our ability to directly compare abundance levels across three decades. In addition, with SCAA the most recent year's population estimates inherently have the widest error bounds, which is to be expected for cohorts that remain at-large under less than full selectivity in the population.

In the SCAA model, population estimates are derived by minimizing an objective function weighted by data sources, including fishery effort, fishery catch, and survey catch rates. In 2011-2012, the YPTG group determined data weightings (referred to as lambdas in ADMB) using an expert opinion approach for evaluating potential sources of bias in data sets that could negatively influence model performance (YPTG 2012). These data weightings were used during 2023 and are presented in Appendix Table 1. The additional recruitment index (generated from the glmulti process) was given a lambda weighting of 1 during the LEPMAG process.

2023 Population Size Projection

The SCAA model was used to project age-2-and-older Yellow Perch stock size in 2023 (Table 1.7). Standard errors and ranges for 2023 projections are provided for each age, and descriptions of minimum, mean, and maximum population estimates refer to the age-specific mean estimates minus or plus one standard deviation (Table 2.2).

Stock size estimates for 2022 (Table 1.7) were higher than those projected last year in MU3 and MU4, and lower in MU1 and MU2 (YPTG 2022). The largest difference was in MU1 where the 2022 age-2 and older abundance was estimated to be 65.791 million fish using the 2022 model, and 32.244 million fish using the 2023 model. The lakewide projection of age-2 and older fish using 2021 data was 173.584 million age-2 and older Yellow Perch in 2022 (YPTG 2022), while estimates using 2022 data in the 2023 model run estimated 2022 abundance of age-2 and older Yellow Perch at 146.398 million fish. Lakewide abundance of age-2-and-older Yellow Perch in 2023 is projected to be 155.251 million fish, an increase of 6% from 2022 estimates.

Abundance projections for 2023 are 53.028, 36.365, 56.912, and 8.947 million age-2-and-older Yellow Perch in management units 1 through 4, respectively. Abundance of age-2-and-older Yellow Perch in 2023 are projected to decrease in MU3 (-17%) and MU4 (-22%) and to increase by 51% in MU1 and 16% in MU2, relative to the 2022 abundance estimates (Table 1.7, Figure 1.9).

Projected age-2 Yellow Perch recruitment in 2023 (the 2021 year class) was 36.128, 16.520, 14.648, and 2.270 million fish in management units 1 through 4, respectively (Table 1.7.).

Age-3-and-older Yellow Perch abundance in 2023 is projected to be 16.900, 19.845, 42.264, and 6.677 million fish in MUs 1 through 4, respectively. Abundance for age-3-and-older Yellow Perch for 2023 are projected to increase from the 2022 estimates in MU1 through MU4 by 38%, 25%, 10%, and 42%, respectively.

As a function of population abundance and mean weight-at-age from fishery-independent surveys, total biomass of age-2-and-older Yellow Perch for 2023 are projected to increase in management units 1 - 4 by 43%, 37%, 4% and 4%, respectively, compared to 2022 estimates (Figure 1.10).

Estimates of Yellow Perch survival for age-3-and-older in 2022 were 30%, 60%, 58%, and 51% in MUs 1 through 4, respectively (Figure 1.11). Estimates of Yellow Perch survival in 2022 for age-2-and-older fish were: 48% in MU1, 63% in MU2, 62% in MU3, and 59% in MU4. Estimated exploitation rates of ages-3-and-older Yellow Perch in 2022 were 47%, 9%, 11%, and 19% in management units 1 through 4, respectively. Estimates of Yellow Perch exploitation for ages-2-and-older fish in 2022 were: 24% in MU1, 5% in MU2, 6% in MU3, and 10% in MU4 (Figure 1.12). Exploitation rate for ages-2-and-older fish in MU2 during 2021 and 2022 were the lowest in the 48 year time series.

Charge 2: Harvest Strategy and Recommended Allowable Harvest

In 2023 the YPTG applied the harvest control rules finalized by the LEC and LEPMAG in 2020. The harvest control rules are comprised of:

- Target fishing mortality as a percent of the fishing mortality at maximum sustainable yield (F_{msy})
- Limit reference point of the biomass at maximum sustainable yield (B_{msv})
- Probabilistic risk tolerance, P-star, P*=0.20

• A limit on the annual change in TAC of ± 20% (when P(SSB<B_{msy})<P*); see Yellow Perch Management Plan, Lake Erie Committee, 2020.

Target fishing rates and limit reference points are estimated annually using SCAA model results. Estimating reference points and recommended allowable harvest is a three-step process. First, estimated recruitment and spawning stock biomass from the SCAA model, along with maturity, weight, and average selectivity at age, are entered into an ADMB model that: 1) estimates the parameters of a Ricker stock-recruitment model and 2) calculates the theoretical spawning stock biomass without fishing (SSB₀). The stock-recruitment relationships for management units 1, 2, and 3, are fit using a hierarchical framework, while management unit 4 is fit independently. In the second step, maturity, weight, and average selectivity at age, along with the parameters of the stock-recruitment relationship are entered in an R-based model. This model estimates F_{msy} and B_{msy} for the harvest control rule. Finally, F_{msy}, F_{target} (as a percent of F_{msy}), and B_{msv} (as a percent of SSB₀), are entered into the PR ADMB model to estimate RAH in each management unit. If the model estimates that fishing at F_{target} meets or exceeds a 0.20 probability (P*) that the projected spawning stock biomass will be less than the limit reference point (B_{msv}), then the fishing rate is reduced until the probability is less than 0.20. Values of SSB₀, B_{msy}, F_{msy}, and F_{target} for each management unit can be found in Table 2.1. Target fishing rates are applied to population estimates and their standard errors to determine minimum, mean, and maximum RAH values for each management unit (Tables 2.2 and 2.3). In addition, RAH values may be subject to a $\pm 20\%$ limit on the annual change in TAC when P(SSB<B_{msy}) < 0.20 (ie: when P* harvest control rule is not invoked).

Quota allocation by management unit and jurisdiction for 2023 was determined by the same methods applied in 2009-2022, using GIS applications of jurisdictional surface area of waters within each MU (Figure 2.1). The allocation of shares by management unit and jurisdiction are:

Allocation	of TAC	within Mana	agement U	Init and Jur	isdiction,	<u> 2023:</u>
<u>MU1</u> :	ONT	40.6%	OH	50.3%	MI	9.1%
MU2:	ONT	45.6%	ОН	54.4%		
MU3:	ONT	52.3%	ОН	32.4%	PA	15.3%
MU4:	ONT	58.0%	NY	31.0%	PA	11.0%

Charge 3: Utilize existing population models to produce the most scientifically defensible and reliable method for estimating and forecasting abundance, recruitment, and mortality.

In 2021 the Ohio fall trawl survey was not conducted due to a boat malfunction, this resulted in the loss of one year of age 2 and older data from this data set in the ADMB model. In 2022, the YPTG updated the MU1 model to account for a missing year of data in the Ohio trawl survey. In order to evaluate the impacts of the missing year of data, the 2022 model was run assuming that the survey did not occur in 2020 and using fabricated 2021 data. Changes to model estimates were negligible, and the 2023 MU1 model was run with Ohio trawl survey data from 1990 to 2020 and 2022 (missing 2021).

The YPTG has been using the current configuration of the ADMB model for 5 years. It has been found that abundance estimates in the last year of the ADMB model often decrease between the first estimate in the model and subsequent years estimates in the model. On average age 2 estimates for the various MUs decrease between 9% and 42% from the first time they are estimated by the model to the second time they are estimated by the model. This change was especially pronounced in MU1 during this year's model run. Further, age 2 estimates decrease an average of 26% to 58% between the first time they are estimated by the model to the third time they are estimated by the model, with the lowest change occurring in MU4 and the highest in MU1. Changes in random walk catchability estimates between model runs can contribute to changes in abundance estimates, with increases in catchability leading to reduced abundance estimates. Constant selectivity in the model may contribute to different abundance estimates, as changes in selectivity will not be recognized by the model when they occur. Additional work is required to evaluate retrospective patterns in model results and their causes.

Charge 4. Supply needed technical support throughout the upcoming YPMP review process

The Yellow Perch Management Plan (YPMP) runs from 2020 to 2024. A review of YPMP will begin in 2023. The review will evaluate the existing Yellow Perch assessment model and the harvest control rule. During 2022, the YPTG identified several aspects of the YPMP to incorporate into the review, including: the use of the recruitment survey data in the assessment model, methods used to estimate catchability and selectivity, the data used in the stock recruit relationship to estimate the reference points, and the harvest control rules including how to implement fishing when population abundance is low.

Acknowledgments

The task group members wish to thank the following people for providing support to the task group during the past year:

- Dr. Travis Brenden of Michigan State University's Quantitative Fisheries Center
- Ann Marie Gorman of the Ohio Department of Natural Resources, Division of Wildlife
- Karen Soper of the Ontario Ministry of Natural Resources and Forestry
- Dr. Richard Kraus of the U.S. Geological Survey, Biological Resources Division, Sandusky

The YPTG report could not be completed without the contributions of all Lake Erie staff from the Michigan Department of Natural Resources, Ohio Division of Wildlife, Pennsylvania Fish and Boat Commission, New York Department of Environmental Conservation, US Geological Survey – Biological Resources Division, and the Ontario Ministry of Natural Resources and Forestry. In addition, the YPTG expresses our thanks to the Great Lakes Fishery Commission for their continued support.

⁽a) sport effort in angler-hours; gill net effort in km; trap net effort in lifts

⁽b) harvest rates for sport in fish/hr, gill net in kg/km, trap net in kg/lift

⁽c) the Ontario sport fishery harvested approximately 21,361 lbs of yellow perch in the 2014 creel survey

^(*) large mesh catch rates are not targeted and therefore of limited value

(a) Spawning stock biomass when population is fished at target fishing rate
 (b) In MU2 fishing at F_{larget} exceeds a 0.20 probability (P*) that the projected spawning stock biomass will be equal to or less than the limit reference point (B_{msy}), therefore the fishing rate was reduced until the probability was less than 0.20.

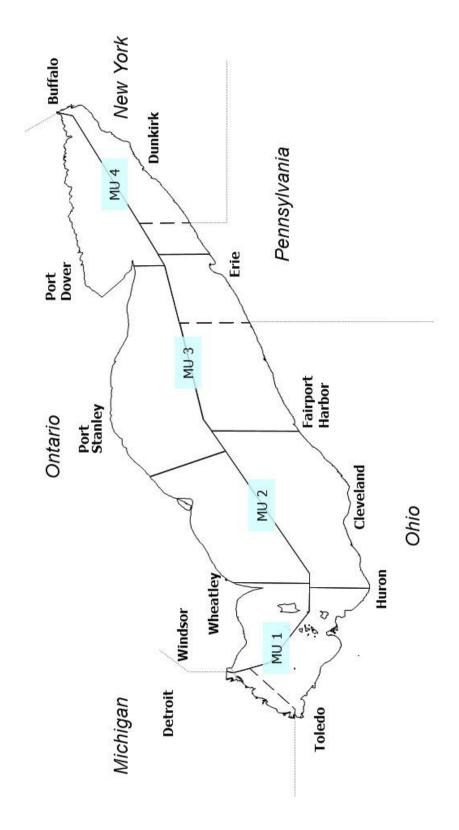

Estimated harvest of Lake Erie Yellow Perch for 2023 using the proposed fishing policy and selectivity-at-age from combined fishing gears. **Table 2.2.**

(a) In MU2 fishing at F_{larget} exceeds a 0.20 probability (P*) that the projected spawning stock biomass will be equal to or less than the limit reference point (B_{nsy}), therefore the fishing rate was reduced until the probability was less than 0.20.

Table 2.3. Lake Erie Yellow Perch fishing rates and the Recommended Allowable Harvest (RAH; in millions of pounds) for 2023 by Management Unit (Unit). RAH values may be subject to a limit on the annual change in TAC (±20%).

Appendix Table 4. Lakewide trawl index codes and series names used in Appendix Tables 2 and 3.

All series are reported in arithmetic mean catch per hectare, except LPS41, NYGN41, and OPSF11-41, gill net indices which are reported in mean catch per lift. Abbreviations in Appendix Table 3 ending with a 'B represent survey indices blocked by depth strata.

Reasons for inclusion or exclusion of surveys from the multi-model inference (MMI) process are included.

Abbreviation	Series		Reason for inclusion / exclusion (for next 5 years
		MMI process	or until further research assessment)
OHS10	Ohio Management Unit 1 summer age 0	no	Data used in OOS10
OHS11	Ohio Management Unit 1 summer age 1	no	Data used in OOS11
011011	Ohio Management Unit 1 fall		consistent collection, broad spatial coverage, high selectivity, reduced
OHF10	age 0	yes	mortality influence
OUE11	Ohio Management Unit 1 fall		consistent collection, broad spatial coverage, high selectivity, reduced mortality influence, temporally adjacent to spring Age-2 abundance (the
OHF11	age 1	yes	target prediction)
OOS10	Ontario/Ohio Management Unit 1 summer age 0	yes	consistent collection, broadest spatial coverage, high selectivity, reduced mortality influence
OOS11	Ontario/Ohio Management Unit 1 summer age 1	yes	consistent collection, broadest spatial coverage, high selectivity, reduced mortality influence, temporally adjacent to spring Age-2 abundance (the target prediction)
00011	Ohio Management Unit 2	7	hypoxic, 26 indices in 28 years, higher variability, low selectivity,
OHS20	summer age 0	no	influenced from mortality,
OHF20	Ohio Management Unit 2 fall age 0	yes	normoxic, 28 indices in 28 years, broad spatial coverage, lower variability, high selectivity, reduced mortality influence
0111 20	age o	yes	hypoxic, 26 indices in 28 years, higher variability, high selectivity,
	Ohio Management Unit 2		reduced mortality influence, temporally adjacent to spring Age-2
OHS21	summer age 1	no	abundance (the target prediction)
	01: 4		normoxic, 28 indices in 28 years, broad spatial coverage, lower
OHF21	Ohio Management Unit 2 fall age 1	yes	variability, high selectivity, reduced mortality influence, temporally adjacent to spring Age-2 abundance (the target prediction)
OHIZI	Ohio Management Unit 3	yes	hypoxic, 25 indices in 28 years, higher variability, low selectivity,
OHS30	summer age 0	no	influenced from mortality,
	Ohio Management Unit 3 fall		normoxic,28 indices in 28 years, broad spatial coverage, lower
OHF30	age 0	yes	variability, high selectivity, reduced mortality influence
			hypoxic, 25 indices in 28 years, higher variability, high selectivity,
	Ohio Management Unit 3		reduced mortality influence, temporally adjacent to spring Age-2
OHS31	summer age 1	no	abundance (the target prediction)
	Ohio Managanant Hait 2 fall		normoxic, 28 indices in 28 years, broad spatial coverage, lower
OHF31	Ohio Management Unit 3 fall age 1	yes	variability, high selectivity, reduced mortality influence, temporally adjacent to spring Age-2 abundance (the target prediction)
0111 31	age 1	yes	normoxic, consistent collection, broad spatial coverage, lower variability,
	Ohio Management Unit 2 June		high selectivity, reduced mortality influence, temporally adjacent to
OHJ21	age 1	yes	spring Age-2 abundance (the target prediction)
			normoxic, consistent collection, broad spatial coverage, lower variability,
	Ohio Management Unit 3 June		high selectivity, reduced mortality influence, temporally adjacent to
OHJ31	age 1	yes	spring Age-2 abundance (the target prediction)
	Ohio Management Unit 2 July		some hypoxic, 23 indices in 28 years, higher variability, low selectivity,
OHJY20	age 0	no	influenced from mortality,
ОНЈҮ30	Ohio Management Unit 3 July age 0	no	some hypoxic, 23 indices in 28 years, higher variability, low selectivity, influenced from mortality,
001010	uge 0	110	some hypoxic, 23 indices in 28 years, higher variability, high
	Ohio Management Unit 2 July		some hypoxic, 23 indices in 28 years, higher variability, high selectivity, reduced mortality influence, temporally adjacent to spring
OHJY21	age 1	no	Age-2 abundance (the target prediction)
			some hypoxic, 23 indices in 28 years, higher variability, high
	Ohio Management Unit 3 July		selectivity,reduced mortality influence, temporally adjacent to spring
OHJY31	age 1	no	Age-2 abundance (the target prediction)
OLDNI40	Outer Long Point Bay Nearshore	ro.	Data used in LPC40
OLPN40	Management Unit 4 age 0	no	Data used in LPC40
	Outer Long Point Bay Nearshore		

Appendix Table 4 continued

Abbreviation	Series	Used in 2023 MMI process	Reason for inclusion / exclusion (for next 5 years or until further research assessment)
OLPO40	Outer Long Point Bay Offshore Management Unit 4 age 0	no	Data used in LPC40
OLFO40	Outer Long Point Bay Offshore	no no	
OLPO41	Management Unit 4 age 1	no	Data used in LPC41
ILPF40	Inner Long Point Bay Management Unit 4 age 0	no	Data used in LPC40
ILPF41	Inner Long Point Bay Management Unit 4 age 1	no	Data used in LPC41
LPC40	Long Point Composite Management Unit 4 age 0	yes	The composite index is the most complete indicator of the state of age-0 yellow perch in Long Point Bay, as it encompasses all depth strata and has greater spatial coverage.
LPC41	Long Point Composite Unit 4 age 1	yes	The composite index is the most complete indicator of the state of age-1 yellow perch in Long Point Bay, as it encompasses all depth strata and has greater spatial coverage.
LPS41	Long Point Bay Management Unit 4 summer Gill Net age 1	no	Exclude from model due to change in survey design 2018
NYF40	New York Management Unit 4 fall trawl age 0	yes	This continuous 28-year index, has broad spatial coverage, consistent methodology, and is the only age-0 recruitment index for the south shore waters of MU4
NYF41	New York Management Unit 4 fall trawl age 1	yes	This continuous 28-year index, has broad spatial coverage, consistent methodology, and is one of two age-2 recruitment indicies for the south shore waters of MU4
NYGN41	New York Management Unit 4 gill net age 1	yes	This continuous 27-year index, has broad spatial coverage, consistent methodology, and is one of two age-2 recruitment indicies for the south shore waters of MU4
OPSF11	Ontario Partnership Gill Net Management Unit 1 fall age 1	yes	West basin age 1 index gill net catch rate (bottom nets) adjusted to equal effort among mesh sizes and for size selective bias of mesh configuration (Helser et al. 1998 normal gillnet selectivity retention curve); N usually 22 most years September
OPSF21	Ontario Partnership Gill Net Management Unit 2 fall age 1	yes	West central basin age 1 index gill net catch rate (bottom nets) adjusted to equal effort among mesh sizes and for size selective bias of mesh configuration (Helser et al. 1998 normal gillnet selectivity retention curve); N usually 36 Most years Oct, Nov
OPSF31	Ontario Partnership Gill Net Management Unit 3 fall age 1	yes	East central age 1 basin index gill net catch rate (bottom nets) adjusted to equal effort among mesh sizes and for size selective bias of mesh configuration (Helser et al. 1998 normal gillnet selectivity retention curve); N usually 36, Most years Oct, Nov
OPSF41	Ontario Partnership Gill Net Management Unit 4 fall age 1	yes	East basin index age 1 gill net catch rate (bottom nets < 30 m) adjusted to equal effort among mesh sizes and for size selective bias of mesh configuration (Helser et al. 1998 normal gillnet selectivity retention curve); N usually 20 @ depths < 30m, Most years Aug-Sep
MIS10	Michigan Management Unit 1 summer trawl age 0	no	West basin age 0 trawl index conducted during August, susrvey begins in 2014. Excluded from model due to short time series
MIS11	Michigan Management Unit 1 summer trawl age 1	no	West basin age 1 trawl index conducted during August, susrvey begins in 2014. Excluded from model due to short time series
